

Q2. Is there any relationship between individual characteristics (sex, age, health insurance) and specific health problems?

KEY FINDING

Diagnosis groups discharges distribution showed more contrast across age groups, while differences by sex and insurance were noticeable smaller.

KEY INSIGHTS

- Diagnosis groups showed greater variation across age ranges than sex or insurance categories.
- Flu and pneumonia is the only group where both children and older adults are affected by this health problem in a relatively high proportion at the same time.
- In general, the biggest proportion of discharges per diagnosis group tend to be from either younger or older, not middle aged patients
- Sex differences were primarily driven by sex-specific diagnoses.

WHY IT MATTERS

Understanding how individual characteristics play a role in the prevalence of different health issues is important to design targeted prevention strategies and anticipate possible consequences due to demographic and socioeconomic changes.

INTERPRETATION

The findings suggest that age is a major determinant of hospital discharge patterns. The observed dynamic indicates that demographic changes, particularly population ageing are shaping healthcare demand.

LIMITATIONS & NEXT STEPS

Limitations:

- The analysis identifies associations between patient characteristics and diagnosis groups but does not establish causal relationships.

Next Steps:

- Assess how demographic changes, particularly population aging, may influence future hospital demand.
