

Q1. Evolution of Hospital Discharge Prevalence by Diagnosis Group (2001–2025)

KEY FINDING

Diagnosis groups with high variability tend to reduce their prevalence over the years, while obesity and related conditions increased substantially, rising from 0.02% in 2005 to more than 2% in 2025.

KEY INSIGHTS

- Covid-19 shows the highest short-term variability due to the pandemic.
- Most diagnosis groups show stable or declining prevalence.
- Obesity and similar diseases increase substantially, reaching a prevalence of 2.2%.
- Cardiopulmonary disease reach around 0.45% of prevalence with a high volatility

WHY IT MATTERS

Understanding the evolution of hospital prevalence of health issues over the time helps policymakers and healthcare organizations anticipate future resource needs and emerging public health challenges.

INTERPRETATION

The observed patterns suggest a shift from infectious conditions toward chronic, lifestyle-related diseases. The rapid growth of obesity-related diagnoses may reflect demographic and behavioral changes and could increase pressure on healthcare services.
